# Matrix elements with a two-hadron final state: Lellouch-Lüscher relations 

Harvey Meyer

Scattering from the Lattice: applications to phenomenology and beyond, Trinity College, Dublin, 14 May 2018

## Outline

Lecture 1: Within Quantum Mechanics, relate the spectrum and matrix elements calculated on an $L \times L \times L$ torus to scattering phases and transition amplitudes.

Lecture 2: Relativistic exclusive processes: the $K \rightarrow \pi \pi$ decay; and $e^{+} e^{-} \rightarrow \pi \pi$ and applications to $(g-2)_{\mu}$

Lecture 3: Probing inclusive transition rates in lattice QCD.
"Scattering of particles leaves an imprint on stationary observables; our task is to decipher that imprint."

## Why QM?

It is instructive.
An approach to particle scattering that does not work in QM will surely not work in relativistic QFT.

In two-body scattering, it has been shown that the QFT case can be reduced to a QM problem in the c.m. frame à la
$-\frac{1}{2 \mu} \triangle \psi(\boldsymbol{r})+\frac{1}{2} \int d^{3} r^{\prime} U_{\mathcal{E}}\left(\boldsymbol{r}, \boldsymbol{r}^{\prime}\right) \psi\left(\boldsymbol{r}^{\prime}\right)=\mathcal{E} \psi(\boldsymbol{r}), \quad$ 2-particle energy $=2 \sqrt{m^{2}+m \mathcal{E}}$
M. Lüscher, Commun. Math. Phys. 105, 153-188 (1986)

## 1d case: scattering states on the circle

[Lüscher Comm.Math.Phys. 105, 153 (1986)]
Consider a one-dimensional QM problem,

$$
\begin{aligned}
\psi(x, y)=f(x-y) & =f(y-x) \\
\left\{-\frac{1}{m} \frac{d^{2}}{d z^{2}}+V(|z|)\right\} f(z) & =E f(z)
\end{aligned}
$$

Scattering state: for $E=k^{2} / m, k \geq 0$, choose

$$
f_{E}(z) \stackrel{|z| \rightarrow^{\infty}}{\sim}(1+\ldots) \cos (k|z|+\delta(k))
$$

- now consider a finite periodic box, $L \gg$ range of $V$
- $V_{L}(z)=\sum_{\nu \in \mathbb{Z}} V(|z+\nu L|)$
- in leading approx., $f_{E}(z)$ unchanged, but quantization condition:

$$
f_{E}^{\prime}\left(-\frac{L}{2}\right)=f_{E}^{\prime}\left(\frac{L}{2}\right)=0 \quad \Rightarrow \quad \frac{1}{2} k L+\delta(k)=\pi n, \quad n \in \mathbb{Z}
$$

Generalization to 3d?

## Lüscher's condition: quantum mechanics analysis (I)

M. Lüscher B354 (1991) 531

Two spinless particles in the final state, interacting via a short-range potential of range $R$; reduced mass $\mu=\left(1 / m_{1}+1 / m_{2}\right)^{-1}$.
A. Scattering state in infinite volume in the rest frame: wavefunction $\psi\left(\boldsymbol{x}_{1}-\boldsymbol{x}_{2}\right)$

For $r>$ interaction range, $\psi$ satisfies the free stationary Schrödinger equation (i.e. the Helmholtz equation)

$$
\left(\triangle+k^{2}\right) \Psi(\boldsymbol{r})=0, \quad E=\frac{k^{2}}{2 \mu}
$$

Solution via spherical Bessel functions,

$$
\psi(\boldsymbol{r})=Y_{\ell m}(\theta, \phi)\left(\alpha_{\ell}(k) j_{\ell}(k r)+\beta_{\ell}(k) n_{\ell}(k r)\right), \quad r>R .
$$

Scattering phase $\delta_{\ell}$ for final state with angular momentum $\ell$ :

$$
e^{2 i \delta_{\ell}}=\frac{\alpha_{\ell}(k)+i \beta_{\ell}(k)}{\alpha_{\ell}(k)-i \beta_{\ell}(k)} .
$$

## Lüscher's condition: quantum mechanics analysis (II)

B. On the $L \times L \times L$ torus, state with total momentum $\boldsymbol{P}=0$ : relative motion described by wave function $\Psi(\boldsymbol{r})$.
For $L / 2>r>R, \Psi$ satisfies again the Helmholtz equation, but different boundary condition. Let

$$
\Gamma=\left\{\boldsymbol{p} \left\lvert\, \boldsymbol{p}=\frac{2 \pi}{L} \boldsymbol{n}\right., \boldsymbol{n} \in \mathbb{Z}^{3}\right\} .
$$

The fundamental solution, is (for $k$ such that the denominator never vanishes)

$$
G\left(\boldsymbol{r} ; k^{2}\right)=\frac{1}{L^{3}} \sum_{\boldsymbol{p} \in \Gamma} \frac{e^{i \boldsymbol{p} \cdot \boldsymbol{r}}}{\boldsymbol{p}^{2}-\boldsymbol{k}^{2}}, \text { satisfying }-\left(\triangle+k^{2}\right) G\left(\boldsymbol{r} ; k^{2}\right)=\delta_{L}^{(3)}(\boldsymbol{r})
$$

The state belongs to an irreducible representation of the cubic group. For instance, for the $T_{1}$ irrep containing the $\ell=1,3, \ldots$ waves, one solution is

$$
\Psi(\boldsymbol{r})=v_{1,0} G_{1,0}\left(\boldsymbol{r}, k^{2}\right)=\frac{1}{2 L^{3}} \sqrt{\frac{3}{\pi}} v_{1,0} \frac{\partial}{\partial z} \sum_{\boldsymbol{p} \in \Gamma} \frac{e^{i \boldsymbol{p} \cdot \boldsymbol{r}}}{\boldsymbol{p}^{2}-\boldsymbol{k}^{2}} .
$$

## Origin of the quantization condition

For given energy $E$, the angular momentum $\ell$ component of the wave-function is uniquely determined up to normalization, because

- the regular solution in the region $0<r<R$ for given energy $E$ is unique up to overall normalization;
- it determines the value and derivative of $\psi_{\ell=1}(r=R)$;
- this then uniquely determines the wave function for $r>R$ (initial-value 2nd order ODE).
Therefore, the angular momentum $\ell$ component of the finite-volume wave-function must be proportional to the infinite-volume wave-function of same energy $E$.

However, directly calculating e.g. the $\ell=1$ component of $G_{1,0}\left(r, k^{2}\right)$, this is not true for fixed $L$ and a randomly chosen $E$; it is true only for discrete values of the energy $\Rightarrow$ quantization condition.

## Math. problem: partial wave decomposition of $G_{\ell, m}\left(r, k^{2}\right)$

Expansion in spherical harmonics is dictated by the geometry of the cube. Since we know the $r$ dependence must be given by $n_{\ell}(k r)$ and $j_{\ell}(k r)$, sufficient to look at $r \rightarrow 0$.
Simplest case:

$$
G\left(\boldsymbol{r}, k^{2}\right) \equiv \frac{1}{L^{3}} \sum_{p \in \Gamma} \frac{e^{i \boldsymbol{p} \cdot \boldsymbol{r}}}{\boldsymbol{p}^{2}-\boldsymbol{k}^{2}}=\underbrace{\frac{k}{4 \pi} n_{0}(k r)}_{r \rightarrow 0:(4 \pi r)^{-1}}+\frac{1}{L} \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} \bar{g}_{\ell m}(q) Y_{\ell_{m}}(\theta, \phi) j_{l}(k r) .
$$

E.g. $\bar{g}_{00}(q) / L=\sqrt{4 \pi} \lim _{r \rightarrow 0}\left(G\left(\boldsymbol{r}, k^{2}\right)-\frac{1}{4 \pi r}\right)$.

Use $\int d t e^{t q^{2}} K(t, \boldsymbol{r})$ type representation of $G\left(\boldsymbol{r}, k^{2}\right)$ with the heat kernel $K(t, \boldsymbol{r})=\frac{1}{L^{3}} \sum_{p \in \Gamma} e^{i \boldsymbol{p} \cdot \boldsymbol{r}-\boldsymbol{p}^{2} t}$.
Result:

$$
\begin{gathered}
\bar{g}_{\ell m}(q)=\frac{i^{\ell}}{\pi q^{\ell}} \mathcal{Z}_{\ell m}\left(1 ; q^{2}\right), \quad q=\frac{k L}{2 \pi} \\
\text { "3d zeta fctn": } \quad \mathcal{Z}_{\ell m}\left(s ; q^{2}\right)=\sum_{\boldsymbol{n} \in \mathbb{Z}^{3}} \frac{\mathcal{Y}_{\ell m}(\boldsymbol{n})}{\left(n^{2}-q^{2}\right)^{s}}, \quad \mathcal{Y}_{\ell m}(\boldsymbol{r}) \equiv r^{\ell} Y_{\ell m}(\theta, \phi) .
\end{gathered}
$$

## Math. problem: PW decomposition of $G_{\ell, m}\left(r, k^{2}\right)$ (II)

Example in the $T_{1}$ irrep:

$$
G_{1, m}(\boldsymbol{r})=-\frac{k^{2}}{4 \pi} Y_{1 m}(\theta, \phi)\left[n_{1}(k r)+\mathcal{M}_{1 m, 1 m}(q) j_{1}(k r)\right]+\text { other partial waves. }
$$

$\mathcal{M}_{\ell m, \ell^{\prime} m^{\prime}}(q)=$ combination of 3d zeta functions and Clebsch-Gordan coefficients.

Compare the expression with infinite-volume wave function

$$
\psi_{1, m}(\boldsymbol{r}) \stackrel{r \geq R}{=} Y_{1, m}(\theta, \phi)\left(\alpha_{1}(k) j_{1}(k r)+\beta_{1}(k) n_{1}(k r)\right)
$$

$\Rightarrow$ quantization condition:

$$
\alpha_{1}(k)-\beta_{1}(k) \mathcal{M}_{1 m, 1 m}(q)=0 .
$$

More generally: $\operatorname{det}[A-B M]=0$.

## The main practical result for the spectrum

Lüscher's condition determining the spectrum in the $A_{1}$ or in the $T_{1}$ representation, neglecting all but the lowest $-\ell$ scattering phase ( $s$ and $p$ wave respectively):

$$
\delta_{\ell}(k)+\phi(q)=n \pi, \quad n \in \mathbb{Z}, \quad q \equiv \frac{k L}{2 \pi} .
$$

$\phi(q)$ a known, continuous kinematic function; $\phi(0)=0$ and

$$
\tan \phi(q)=-\frac{\pi^{3 / 2} q}{\mathcal{Z}\left(1 ; q^{2}\right)}, \quad \mathcal{Z}\left(s ; q^{2}\right)=\frac{1}{\sqrt{4 \pi}} \sum_{n \in \mathbb{Z}^{3}} \frac{1}{\left(\boldsymbol{n}^{2}-q^{2}\right)^{s}} .
$$

Non-relativistic quantum mechanics: $E=\frac{k^{2}}{2 \mu}$.
Not obvious, but in a relativistic theory, the only change is that $E=2 \sqrt{k^{2}+m^{2}}$.

## Analytically continuing zeta functions

For $\operatorname{Re}(s)>1$ :

$$
\zeta(s) \equiv \sum_{n \geq 1} \frac{1}{n^{s}}=\sum_{n \geq 1} \frac{1}{\Gamma(s)} \int_{0}^{\infty} d t t^{s-1} e^{-t n}=\frac{1}{\Gamma(s)} \int_{0}^{\infty} d t \frac{t^{s-1}}{e^{t}-1}
$$

Now

$$
\zeta(s)=\frac{1}{\Gamma(s)}\left\{\int_{0}^{1} d t t^{s-2}+\int_{0}^{1} d t t^{s-1}\left[\frac{1}{e^{t}-1}-\frac{1}{t}\right]+\int_{1}^{\infty} d t \frac{t^{s-1}}{e^{t}-1}\right\}
$$

The analytic continuation to $\operatorname{Re}(s)>0$ can now be performed by replacing $\int_{0}^{1} d t t^{s-2}$ by $\frac{1}{s-1}$.

$$
\sum_{n \in \mathbb{Z}} \frac{1}{\left(n^{2}-q^{2}\right)^{s}}=\sum_{|n|<\lambda} \frac{1}{\left(n^{2}-q^{2}\right)^{s}}+\frac{1}{\Gamma(s)} \int_{0}^{\infty} d t t^{s-1} e^{t q^{2}} \sum_{|n| \geq \lambda} e^{-t n^{2}}
$$

for $\lambda^{2}>\operatorname{Re}\left(q^{2}\right)$. Then proceed in the same way to continue to the region $\operatorname{Re}(s) \leq \frac{1}{2}$.
The case of the $3 \mathrm{~d} \mathcal{Z}_{\ell_{m}}\left(s ; q^{2}\right)$ is analogous.

## Normalization of the states (I)

$\infty$ Vol: $\psi(\boldsymbol{r})=Y_{\ell m}(\theta, \phi)\left(\alpha_{\ell}(k) j_{\ell}(k r)+\beta_{\ell}(k) n_{\ell}(k r)\right), \quad r>$ interaction range Torus: $\Psi(\boldsymbol{r})=v_{1,0} G_{1,0}\left(\boldsymbol{r}, k^{2}\right)=\frac{1}{2 L^{3}} \sqrt{\frac{3}{\pi}} v_{1,0} \frac{\partial}{\partial z} \sum_{p} \frac{e^{i \boldsymbol{p} \cdot \boldsymbol{r}}}{\boldsymbol{p}^{2}-\boldsymbol{k}^{2}}$.

- Lüscher's condition determining the spectrum:

$$
\delta_{\ell}(k)+\phi(q)=n \pi, \quad n \in \mathbb{Z}, \quad q \equiv \frac{k L}{2 \pi}
$$

What value of $v_{1,0}$ normalizes the wavefunction to unity? Use a trick: [Lellouch, Lüscher hep-lat/003023; HM 1202.6675]

$$
\begin{array}{lcc}
\delta_{\ell} & \xrightarrow{(L)} & E_{n}(L) \\
\downarrow \Delta V & & \downarrow \Delta V \\
\delta_{\ell}+\Delta \delta_{\ell} & \xrightarrow{(L)} & E_{n}(L)+\Delta E_{n}(L) .
\end{array}
$$

## Normalization of the states (II)

1st order perturbation theory in quantum mechanics under $V \rightarrow V+\Delta V$ :

$$
\Delta E=\int_{\Omega_{L}} \mathrm{~d}^{3} \boldsymbol{r} \Psi(\boldsymbol{r})^{*} \underbrace{Q_{\Lambda}}_{\text {projector onto } \ell \leq \Lambda} \Delta V_{L}(\boldsymbol{r}) \Psi(\boldsymbol{r})=\frac{d E}{d k} \Delta k .
$$

On the other hand, the change in the phase shift is given by the generalized Born formula (see e.g. Landau \& Lifshitz, Quantum Mechanics, parag. 133), which for an energy-normalized wavefunction takes the form

$$
\Delta \delta_{\ell}=-\pi \int_{0}^{\infty} r^{2} \mathrm{~d} r \Delta V(r)\left|\psi_{\ell m}(r)\right|^{2}
$$

Taking the differential of the quantization condition, the change in the scattering phase is accompanied by a change in the energy level according to

$$
\Delta \delta_{\ell}(k)=-F_{\ell}(k, L) \frac{\Delta k}{k}, \quad F_{\ell}(k, L) \equiv k \frac{\partial \delta_{\ell}(k)}{\partial k}+q \phi^{\prime}(q)
$$

$F_{\ell}(k, L)$ is the Lellouch-Lüscher factor.
Putting these three equations together, we obtain. . .

## Relation between finite- and infinite volume wavefunction

$$
\left|\psi_{1, m}(r)\right|^{2}=\frac{\mathrm{d} k}{\mathrm{~d} E} \cdot \frac{F_{1}(k, L)}{\pi k} \cdot\left|\Psi_{1, m}(r)\right|^{2}, \quad(r<L / 2)
$$

- infinite volume normalization of states:

$$
\psi(\boldsymbol{r} ; E)=Y_{1 m}(\theta, \phi) \psi_{1 m}(r ; E), \quad \int \mathrm{d}^{3} r \psi(r ; E) \psi\left(r ; E^{\prime}\right)=\delta\left(E-E^{\prime}\right)
$$

- finite volume normalization of states:

$$
\begin{array}{lc}
\Psi(\boldsymbol{r})=\sum_{\ell, m} Y_{\ell m}(\Omega) \Psi_{\ell m}(r), & \int_{0}^{L} \mathrm{~d}^{3} \boldsymbol{r}|\Psi(\boldsymbol{r})|^{2}=1 . \\
F_{\ell}(k, L) \equiv k \frac{\partial \delta_{\ell}(k)}{\partial k}+q \phi^{\prime}(q), & E(k)=\frac{k^{2}}{2 \mu} .
\end{array}
$$

## Higher partial-wave content of the finite-volume state

Writing

$$
\Psi(\boldsymbol{r})=v_{1 \bar{m}} G_{1 m}\left(\boldsymbol{r}, k^{2}\right)=v_{1 \bar{m}} \sum_{\ell=1,3, \ldots} Y_{\ell \bar{m}}(\theta, \phi) \Psi_{\ell \bar{m}}(r)
$$

the relation on the previous slide shows that

$$
v_{1 \bar{m}}=-\sqrt{\frac{2 \mu}{F_{1}(k, L)} \frac{\mathrm{d} E}{\mathrm{~d} k}} \frac{4 \pi}{k} \sin \delta_{1} .
$$

For $\ell=3,5, \ldots$,

$$
\Psi_{\ell \bar{m}}(r)=-\frac{k^{2}}{4 \pi} v_{1 \bar{m}} \mathcal{M}_{1 \bar{m}, \ell m}(q) j_{\ell}(k r)
$$

## Coupling the particles to photons [нм, 1202.6675]

Couple the two (interacting) particles to electromagnetic radiation. With

$$
\boldsymbol{R}=\frac{m_{a} \boldsymbol{r}_{a}+m_{b} \boldsymbol{r}_{b}}{M}, \quad \boldsymbol{r}=\boldsymbol{r}_{b}-\boldsymbol{r}_{a} \quad\left(M=m_{a}+m_{b}\right),
$$

the matter-radiation Hamiltonian can be written in the form

$$
H_{\mathrm{kin}}=\frac{1}{2 M}\left(\boldsymbol{P}-\left(e_{a} \boldsymbol{A}_{a}+e_{b} \boldsymbol{A}_{b}\right)\right)^{2}+\frac{1}{2 \mu}\left(\boldsymbol{p}-\mu\left(\frac{e_{b}}{m_{b}} \boldsymbol{A}_{b}-\frac{e_{a}}{m_{a}} \boldsymbol{A}_{a}\right)\right)^{2}
$$

- $\mu=\frac{m_{a} m_{b}}{m_{a}+m_{b}}=$ reduced mass of the two particles
- $\boldsymbol{A}_{c} \equiv \boldsymbol{A}\left(\boldsymbol{r}_{c}\right)$
- $e_{c}$ is the electric charge ( $c=a, b$ )
- the non-vanishing commutation relations are $\left[P_{i}, R_{j}\right]=\left[p_{i}, r_{j}\right]=-i \delta_{i j}$.

## Applying Fermi's golden rule

Transition rate: $\left.\frac{\mathrm{d} P}{\mathrm{~d} t}=2 \pi\left|\left\langle\Psi_{\mathrm{f}}\right| h_{I}\right| \Psi_{\mathrm{i}}\right\rangle\left.\right|^{2} \rho\left(E_{\mathrm{f}}\right)$, where $\rho(E)=\frac{d n}{d E}$ is the density of final states.

FGR assumes $\Psi_{f}$ and $\Psi_{i}$ are unit-normalized. If instead $\left|\Psi_{f}\right\rangle$ is energy-normalized, meaning

$$
\left\langle\Psi_{\mathrm{f}}(E) \mid \Psi_{\mathrm{f}}\left(E^{\prime}\right)\right\rangle=\delta\left(E-E^{\prime}\right)
$$

then $\rho\left(E_{\mathrm{f}}\right)$ can be set to unity.
The transition is forbidden unless spatial momentum is conserved: if $\left|\psi_{\mathrm{f}, \mathrm{i}}\right\rangle=L^{3 / 2}\left|\Psi_{\mathrm{i}, \mathrm{f}}\right\rangle$, can write

$$
\left\langle\psi_{\mathrm{f}}\right| h_{I}\left|\psi_{\mathrm{i}}\right\rangle=(2 \pi)^{3} \delta^{(3)}\left(\boldsymbol{P}-\boldsymbol{P}^{\prime}\right) \cdot A, \quad A=\left\langle\Psi_{\mathrm{f}}\right| h_{I}\left|\Psi_{\mathrm{i}}\right\rangle .
$$

From then on, work with the $\left|\psi_{f, i}\right\rangle$.
In quantum mechanics, $\left\langle\boldsymbol{R} \boldsymbol{r} \mid \psi_{\mathrm{f}}\right\rangle=e^{i \boldsymbol{P}^{\prime} \cdot \boldsymbol{R}} \psi_{\mathrm{f}, \ell}(r) Y_{\ell m}(\theta, \phi)$ with $\int_{0}^{\infty} d r r^{2} \psi_{\mathrm{f}, \ell, E}(r) \psi_{\mathrm{f}, \ell, E^{\prime}}(r)^{*}=\delta\left(E-E^{\prime}\right)$.

## Transition in infinite volume (l)

One-photon transitions driven by the term

$$
h_{I}=-\frac{1}{2}\left\{\boldsymbol{p},\left(\frac{e_{b}}{m_{b}} \boldsymbol{A}_{b}-\frac{e_{a}}{m_{a}} \boldsymbol{A}_{a}\right)\right\}
$$

(and a second term $H_{I}=-\frac{1}{2 M}\left\{\boldsymbol{P}, e_{a} \boldsymbol{A}_{a}+e_{b} \boldsymbol{A}_{b}\right\}$, but the latter is subdominant at long wavelengths).
Consider a transition from an s-wave bound state $\psi_{\mathrm{i}}$ to a final state $\psi_{\mathrm{f}}$ with angular momentum eigenvalues ( $\ell=1, m=\sigma$ ). Using Fermi's Golden Rule, transition rate given by $\left.\frac{\mathrm{d} P}{\mathrm{~d} t}=2 \pi\left|\left\langle\psi_{\mathrm{f}}\right| h_{I}\right| \psi_{\mathrm{i}}\right\rangle\left.\right|^{2} \rho\left(E_{\mathrm{f}}\right)$; divide by the photon flux $(=c)$ to get the cross-section.
Expand photon field in plane waves $\left(\left[a_{\boldsymbol{k}, \sigma}, a_{\boldsymbol{k}^{\prime}, \sigma^{\prime}}\right]=(2 \pi)^{3} \delta^{(3)}\left(\boldsymbol{k}-\boldsymbol{k}^{\prime}\right) \delta_{\sigma \sigma^{\prime}}\right)$ :

$$
\boldsymbol{A}(t, \boldsymbol{r})=\int \frac{d^{3} k \sum_{\sigma}}{(2 \pi)^{3} \sqrt{2 \omega_{k}}}\left(a_{\boldsymbol{k}, \sigma} \boldsymbol{\epsilon}_{\sigma}(\boldsymbol{k}) e^{i(\boldsymbol{k} \cdot \boldsymbol{r}-\omega t)}+a_{\boldsymbol{k}, \sigma}^{\dagger} \boldsymbol{\epsilon}_{\sigma}(\boldsymbol{k})^{*} e^{-i(\boldsymbol{k} \cdot \boldsymbol{r}-\omega t)}\right)
$$

Use $\boldsymbol{\epsilon}_{\sigma} \cdot\left\{\boldsymbol{p}, e^{i \boldsymbol{k} \cdot \boldsymbol{r}}\right\}=2 \boldsymbol{p} \cdot \boldsymbol{\epsilon}_{\sigma}+\mathrm{O}(k)$ and $\boldsymbol{p}=i \mu\left[H_{0}, \boldsymbol{r}\right]$ to write
$h_{I}=\frac{1}{-2} \int \frac{d^{3} k \sum_{\sigma}}{(2 \pi)^{3} \sqrt{2 \omega_{k}}}\left\{a_{\sigma}(\boldsymbol{k}) e^{i\left(\boldsymbol{k} \cdot \boldsymbol{R}-\omega_{k} t\right)}\left(\frac{e_{b}}{m_{b}}-\frac{e_{a}}{m_{a}}\right) 2 i \mu\left[H_{0}, \boldsymbol{r} \cdot \boldsymbol{\epsilon}_{\sigma}(\boldsymbol{k})\right]+\right.$ h.c. $\left.+\mathrm{O}(k)\right\}$

## Transition in infinite volume (II)

Transition matrix element: $\left\langle\boldsymbol{R} \boldsymbol{r} \mid \psi_{\mathrm{i}}\right\rangle=e^{-i \boldsymbol{k} \cdot \boldsymbol{R}} \psi_{\mathrm{i}}(\boldsymbol{r}),\left\langle\boldsymbol{R} \boldsymbol{r} \mid \psi_{\mathrm{f}}\right\rangle=\psi_{\mathrm{f}}(\boldsymbol{r})$

$$
A=-i \mu \frac{1}{\sqrt{2 \omega}}\left(\frac{e_{b}}{m_{b}}-\frac{e_{a}}{m_{a}}\right)\left(E_{\mathrm{f}}-E_{\mathrm{i}}\right) \int \mathrm{d}^{3} \boldsymbol{r} \psi_{\mathrm{f}}(\boldsymbol{r})^{*}\left(\boldsymbol{\epsilon}_{\sigma}\left(\boldsymbol{k}_{\gamma}\right) \cdot \boldsymbol{r}\right) \psi_{\mathrm{i}}(\boldsymbol{r})+\mathrm{O}(k) .
$$

Kinematics of the reaction: $E_{f}-E_{i}=\omega, \boldsymbol{p}_{f}-\boldsymbol{p}_{i}=\boldsymbol{k}$.
Cross section: $\int d^{3} r\left|\psi_{\mathrm{i}}(\boldsymbol{r})\right|^{2}=1, \int d^{3} r \psi_{\mathrm{f}}(\boldsymbol{r} ; E) \psi_{\mathrm{f}}\left(\boldsymbol{r} ; E^{\prime}\right)^{*}=\delta\left(E-E^{\prime}\right)$

$$
\sigma_{\ell m}(\omega)=\delta_{\ell 1} \delta_{m \sigma} \pi \mu^{2}\left(\frac{e_{b}}{m_{b}}-\frac{e_{a}}{m_{a}}\right)^{2} \omega_{\gamma}\left|\boldsymbol{\epsilon}_{\sigma}\left(\boldsymbol{k}_{\gamma}\right) \cdot \boldsymbol{r}_{\mathrm{f}}\right|^{2} \quad \boldsymbol{r}_{\mathrm{fi}} \equiv \int \mathrm{~d}^{3} \boldsymbol{r} \psi_{\mathrm{f}}(\boldsymbol{r})^{*} \boldsymbol{r} \psi_{\mathrm{i}}(\boldsymbol{r}) .
$$

Differential cross-section: prob. to go into $p$-wave $\times$ angular prob. distribution of the $p$-wave $\psi_{\mathrm{f}}(\boldsymbol{r})$

$$
d \sigma=\sigma_{1 \sigma}(\omega)\left|Y_{1, \sigma}(\theta \phi)\right|^{2} d \Omega \propto \sin ^{2}(\theta) d \Omega
$$

## Photodisintegration from matrix elements on the torus

- energy-levels of the final two-particle scattering state are discrete $\Rightarrow$ tune the box size $L$ to have all particles on-shell
- initial state has a radius $r_{s}<L / 2 \Rightarrow$ essentially the only angular momentum component is the s-wave component (up to expt. corr.)
- the position operator is a pure $\ell=1$ operator $\Rightarrow$
- the only partial wave that can be reached is $\ell=1$
- the position-space contributions to $\boldsymbol{R}_{\mathrm{fi}} \equiv\left\langle\Psi_{\mathrm{f}}\right| \boldsymbol{r}\left|\Psi_{\mathrm{i}}\right\rangle$ are localized at $r<r_{s}$
- the matrix element $\boldsymbol{R}_{\mathrm{fi}}$ would be the same as in infinite volume, if the normalization of the $p$-wave component of the final state were the same.

$$
\left|\epsilon_{\sigma}\left(\boldsymbol{k}_{\gamma}\right) \cdot \boldsymbol{r}_{\mathrm{f}}\right|^{2}=\frac{\mathrm{d} k}{\mathrm{~d} E} \cdot \frac{F_{1}(k, L)}{\pi k} \cdot\left|\epsilon_{\sigma}\left(\boldsymbol{k}_{\gamma}\right) \cdot \boldsymbol{R}_{\mathrm{f}}\right|^{2}
$$

i.e.

$$
\sigma(\omega)=4 \pi^{2} \mu^{2}\left(\frac{e_{b}}{m_{b}}-\frac{e_{a}}{m_{a}}\right)^{2} \omega_{\gamma}|A|^{2}, \quad|A|^{2}=\frac{\mathrm{d} k}{\mathrm{~d} E} \cdot \frac{F_{1}(k, L)}{\pi k} \cdot \underbrace{\left.\left|\left\langle\Psi_{\mathrm{f}}\right| h_{I}\right| \Psi_{\mathrm{i}}\right\rangle\left.\right|^{2}}_{\text {on the torus, unit-norm states }}
$$

## Summary of lecture 1

- The quantization condition determining the finite-volume spectrum of two-particle states in terms of the infinite-volume scattering phases is derived. Main technical difficulty stems from expanding a stationary wave on the torus in spherical harmonics.
- Transitions from a bound state to a scattering state: can be computed on the torus at low energies. We saw the case of an electric dipole transition.
- Next lecture: relativistic applications.
