### 1. Bhabha and Møller scattering in scalar QED (30 points)

Consider Bhabha (elastic electron-positron) scattering process  $e^+e^- \rightarrow e^+e^-0$  and Møller (elastic electron-electron) scattering process  $e^-e^- \rightarrow e^-e^-$  at the  $2^{nd}$  order ( $\sim e^2$ ) of perturbation series in scalar QED in the c.m. frame.

- (a) Draw all possible Feynman diagrams at this order (tree-level). Using Feynman rules for the scalar QED (see lecture 14 on the website for details), obtain the respective expressions for the invariant amplitudes  $A^B(s, t)$  and  $A^M(s, t)$  for the tree-level Bhabha and Møller scattering, correspondingly. Observe that the amplitude  $A^B$  is symmetric under crossing  $s \leftrightarrow t$ , while  $A^M$  under  $u \leftrightarrow t$ .
- (b) Find the differential cross sections  $\frac{d\sigma^B}{d\Omega}$  and  $\frac{d\sigma^M}{d\Omega}$  for both processes.
- (c) Noting for fixed  $s$ , the  $t$ -variable only depends on the scattering angle, derive the differential cross sections with respect to  $t$ , i.e. show that

$$\frac{d\sigma}{dt} \equiv \frac{d\sigma}{d\Omega} \frac{d\Omega}{dt} = -\frac{1}{16\pi} \frac{|A|^2}{s(t+u)} \quad (1)$$

Determine the limiting values of  $t$  and try to find the total cross sections  $\sigma^B(s)$  and  $\sigma^M(s)$ . Why are the integrals divergent?

### 2. Compton scattering in scalar QED (120 points)

The Compton ( $e^- \gamma \rightarrow e^- \gamma$ ) scattering amplitude at the  $2^{nd}$  order of the perturbation series in scalar QED was derived in the lectures with the result

$$A = e^2 \epsilon_\lambda^\mu(\hat{q}) \epsilon_{\lambda'}^{\nu}(\hat{q}') \left[ 2g_{\mu\nu} - \frac{(2p+q)_\mu(2p'+q')_\nu}{(p+q)^2 - m^2} - \frac{(2p-q')_\mu(2p'-q)_\nu}{(p-q')^2 - m^2} \right] = A_{\lambda\lambda'}. \quad (2)$$

The photon *helicity* is  $\lambda, \lambda' = \pm 1$ . For a photon traveling along the direction  $\hat{q}' = (\sin \theta, 0, \cos \theta)$ , the respective polarization vector with helicity  $\lambda'$  is given by  $\epsilon_{\lambda'}^\nu(\hat{q}') = \frac{1}{\sqrt{2}}(0, \cos \theta, i\lambda', -\sin \theta)$ .

- (a) Evaluate  $A_{\lambda\lambda'}$  in the laboratory frame,  $p^\mu = (M, \vec{0})$ ,  $q^\mu = \omega_L(1, 0, 0, 1)$ ,  $q'^\mu = \omega'_L(1, \sin \theta_L, 0, \cos \theta_L)$ . The photon energies are related to the invariants via  $\omega_L = \frac{p \cdot q}{m} = \frac{s-m^2}{2m}$  and  $\omega'_L = \frac{p \cdot q'}{m} = \frac{m^2-u}{2m}$ . Obtain the Compton formula

$$\omega'_L = \frac{\omega_L}{1 + \frac{\omega_L}{m}(1 - \cos \theta_L)}. \quad (3)$$

Which terms in the square bracket of Eq.(2) contribute  $A_{\lambda\lambda'}$  in the lab frame and which don't?

- (b) Repeat the calculation in the center-of-momentum frame ( $q^\mu = \omega_{cm}(1, 0, 0, 1)$ ,  $q'^\mu = \omega_{cm}(1, \sin \theta_{cm}, 0, \cos \theta_{cm})$ ,  $p^\mu = (\sqrt{s}, \vec{0}) - q^\mu$ , with the photon energy given by  $\omega_{cm} = \frac{s-m^2}{2\sqrt{s}}$ ). Which terms contribute to  $A_{\lambda\lambda'}$  now?

- (c) To arrive at the (differential) cross section one needs to square the amplitude, sum over the final photon polarizations and average over those of the initial photon, i.e. compute

$$\frac{1}{2} \sum_{\lambda, \lambda' = \pm 1} |A_{\lambda\lambda'}|^2 \quad (4)$$

Compute this in the lab. and c.m. frames.

- (d) Does the result depend on the reference frame if expressed in terms of invariants? Hint: to answer this question, start from frame-specific expressions and arrive at

$$\frac{1}{2} \sum_{\lambda, \lambda' = \pm 1} |A_{\lambda\lambda'}|^2 = 2e^4 \left\{ 1 + \left[ 1 - \frac{2m^2 t}{(s - m^2)(u - m^2)} \right]^2 \right\} \quad (5)$$

- (e) Starting from the invariant expression

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s \omega_{cm}^2} \frac{1}{2} \sum_{\lambda, \lambda' = \pm 1} |A_{\lambda\lambda'}|^2, \quad (6)$$

work your way towards the differential cross sections in the lab frame. Using the Compton formula (3), express the differential

$$dt = \frac{\omega_L'^2}{\pi} d\Omega_L, \quad d\Omega_L = d \cos \theta_L d\phi, \quad (7)$$

obtain the unpolarized differential cross section in the lab frame

$$\frac{d\sigma}{d\Omega_L} = \frac{\alpha^2}{2m^2} \frac{1 + \cos^2 \theta_L}{\left[ 1 + \frac{\omega_L}{m} (1 - \cos \theta_L) \right]^2}, \quad \alpha = \frac{e^2}{4\pi}. \quad (8)$$

Find the low-energy behavior of the differential cross section.

- (f) Do the same as in (e) in the c.m. frame, using

$$dt = \frac{\omega_{cm}^2}{\pi} d\Omega_{cm}, \quad d\Omega_{cm} = d \cos \theta_{cm} d\phi, \quad (9)$$

- (g) Derive the total cross section as function of  $\omega_L$ , integrating (8) over  $\theta_L$ .

### 3. Boundaries of the scattering regions on the Mandelstam plane (50 points)

Obtain the limiting values  $t_{min}$  and  $t_{max}$  as functions of other available invariants for the  $2 \rightarrow 2$  processes listed below. Plot them on the  $(s - u, t)$  plane for each case:

- (a) Real Compton scattering  $\gamma(q) + e^-(p) \rightarrow \gamma(q')e^-(p')$  with  $q^2 = q'^2 = 0$ ,  $p^2 = p'^2 = m^2$
- (b) Virtual Compton scattering with a *spacelike* initial photon (originating from e.g. an electron scattering process)  $\gamma^*(q) + e^-(p) \rightarrow \gamma(q')e^-(p')$  with  $q^2 = -Q^2 < 0$ ,  $q'^2 = 0$ ,  $p^2 = p'^2 = m^2$ .
- (c) Virtual Compton scattering with a *timelike* initial photon (originating from e.g.  $e^+e^-$  annihilation)  $\gamma^*(q) + e^-(p) \rightarrow \gamma(q')e^-(p')$  with  $q^2 = Q^2 > 0$ ,  $q'^2 = 0$ ,  $p^2 = p'^2 = m^2$ .
- (d) Doubly-virtual Compton scattering with *one spacelike and one timelike* photon  $\gamma^*(q) + e^-(p) \rightarrow \gamma^*(q')e^-(p')$  with  $q^2 = -q'^2 = -Q^2 < 0$ ,  $p^2 = p'^2 = m^2$ .

Hint: for each reaction write down the constraint on the Mandelstam invariants  $s + t + u = \sum_i p_i^2$ . Remember that  $t_{min}(t_{max})$  are Lorentz invariants and do not depend on the frame. Hence, to find  $t_{min}(t_{max})$  work in your favorite reference frame and put  $\theta = 0$  ( $\theta = \pi$ ), respectively.
